## Real Options for Integrating Unmanned Aircraft into the National Airspace System

Graphic from MIT/LL briefing provided to 303 AESW/XR, May 2007.

# Background

- Growing need for Department of Defense to fly unmanned aircraft for training and operations within the national airspace system
- Unmanned aircraft need to be further developed to meet regulatory requirements for integrated flight
- Significant uncertainty exists in both the cost and performance needed to achieve integrated operations
- This analysis seeks to address the impact of this uncertainty on the system design

# Options Development

- Option 1: Pursue a top-down engineering design with significant upfront effort
  - ↪ Intensive requirements definition phase
  - ↪ Attempt to proceed directly from no access to significant access
- Option 2: Employ an empirical approach by fielding as rapidly as possible
  - ↪ Puts out the current state-of-the-engineering as quickly as possible
  - ↪ Iterates on the design as quickly as possible, feeding results from previous iteration into the next
- Option 3: Flexible framework that seeks to field system quickly, but with foresight towards later requirements
  - ↪ Seeks to integrate a design for immediate employment with an approach for future extensibility to minimize “switching” costs

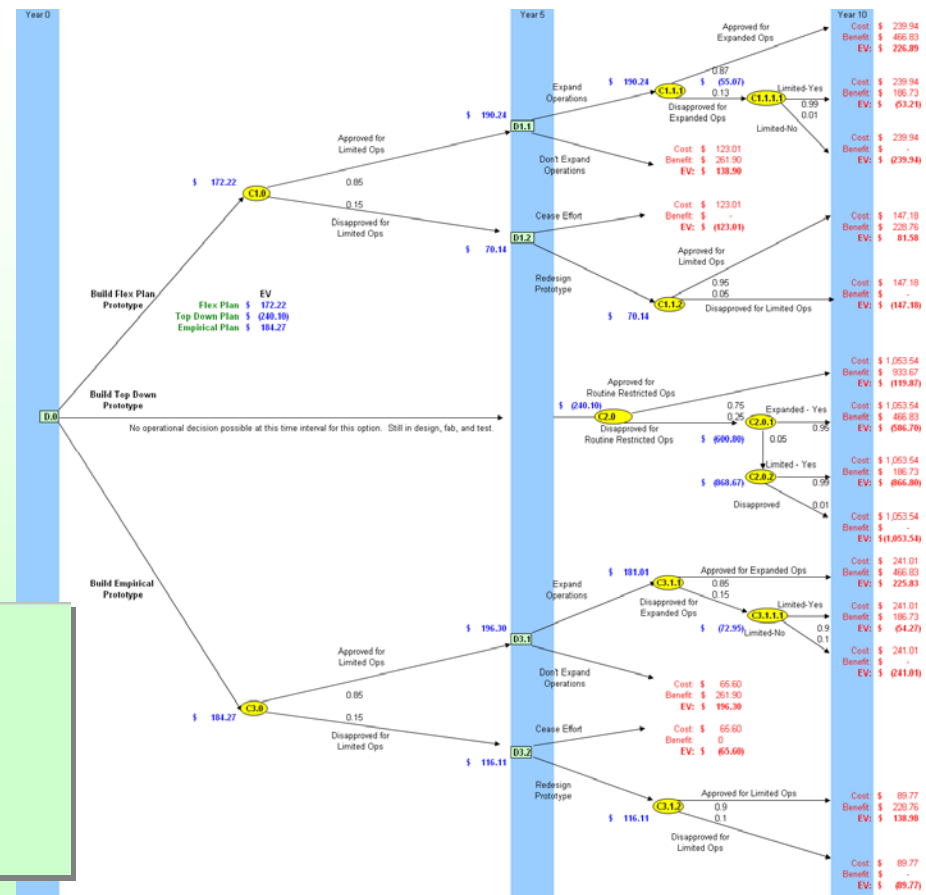

# Uncertainty Development

- Probability of FAA approval for unmanned aircraft operations
  - ↪ Treated as an exogenous system variable
  - ↪ Is path dependent: the way you get there matters
  - ↪ Will use decision tree analysis to evaluate impact
- Uncertainty in potential revenue base
  - ↪ Manned aircraft operations serve as the mission unmanned aircraft will “replace” with corresponding revenue swap
  - ↪ Cost of manned operations is not constant, and may vary dramatically over the develop phase of the unmanned aircraft capability

# Decision Tree Analysis

- Each option evaluated over two decision periods
- Decision period equal to 5 years cycle time
- UAS NRE costs only

Expected NPV	
Flex Plan	\$ 172.22
Top Down Plan	\$ (240.10)
Empirical Plan	\$ 184.27

# Conclusions – UAS Specific Findings

- The potential value of addressing uncertainty in key design factors is substantial
- The AF should approach the problem in a parametric sense--which set of options provides the best investment over what range of values
- The AF should give specific thought to the utility gained from less than total access and quantify the operational utility of additional flexibility

# Conclusions – UAS Specific Findings

- A sensitivity analysis should be performed to focus on a subset of high impact variables to investigate
  - ↳ The high complexity of the effort suggests the analysis would benefit from applying Wang's option identification process to narrow the trade space
  - ↳ Analysis on R&D costs and utility of partial access should be done to determine how well they need to be characterized for a reasonable answer
- Discussions with the FAA on how this approach could impact flight authorization should be accomplished as soon as possible

# Conclusions – General Observations

- Different types of uncertainties require different approaches and tools
- Even a small amount of information with reasonable assumptions about the uncertainty can provide significant insights into design values
- A synthesis of the decision tree and the binomial lattice approaches into a single analysis tool would provide significant benefit for this kind of option analysis
